Abstract

Piezoelectric Film is an enabling transducer technology with unique capabilities. Piezoelectric Film produces voltage in proportion to compressive or tensile mechanical stress or strain, making it an ideal dynamic strain gage. It makes a highly reliable, low-cost vibration sensor, accelerometer or dynamic switch element. Piezoelectric Film is also ideally suited for high fidelity transducers operating throughout the high audio (>1kHz) and ultrasonic (up to 100MHz) ranges. The Piezoelectric Film can become a power source that can be used to power another device. By flexing the PVDF film a voltage is created, that voltage can then be captured and stored until needed.

Research Objective

Our objective states that we will determine whether or not a correlation exists between wind velocity and voltage output from our Piezoelectric (PVDF) film sensor attached to a High Visibility Marking Flag. In order for us to determine this correlation it is important to isolate and define the variables we want to evaluate during the testing procedure. The independent variable will be the wind velocity in which we will be able to increase and vary the wind velocity using a wind tunnel. The dependent variable will be the voltage output produced in response to the wind velocity. Our approach for collecting the data will be to use a Vernier Differential Voltage Probe to collect and plot the voltage data in the Logger Pro Software.

Background

Inspired by Feynman's concepts, K. Eric Drexler independently used the term "nanotechnology" in his 1986 book *Engines of Creation: The Coming Era of Nanotechnology*, which proposed the idea of a nanoscale "assembler" which would be able to build a copy of itself and of other items of arbitrary complexity with atomic control. Since that time Build it smaller; Build it to operate faster; Build it to use less energy has been the mantra of industry. The batteries have gotten smaller but the energy requirements gotten even smaller. Thus the need to identify a low voltage, low cost renewable power supply.

Methodology

This test is not a pass/fail. It is a data collection test. The test sample will be inserted into a wind tunnel and set at low velocity (1mps). Data will be collected for 10 seconds after the wind tunnel has stabilized. The velocity will be increased in units of 1mps and re-tested. Testing will continue thru 8mps. Repeat the testing three times. The test will terminate in the event that the flag or the base is moved by the wind velocity.

Abstract: Energy harvesting techniques using piezoelectric materials have been rapidly developed in the world. In our previous work, we had a kind of elastic energy harvester using a piezoelectric material was proposed and developed; the harvester was called Flexible Piezoelectric Device (FPED). The FPED was applied to wave and current energy, wind energy and vibration energy. In this study, improving the FPED, a new type of wind energy harvester was proposed and developed to generate electric power from broad band of wind velocity, especially low wind and breeze. The energy harvester consists of a piezoelectric material and a thin soft material, which is Flexible Piezoelectric Sheet (FPS) for wind energy harvesting. The theoretical approach was provided using a classical

Results and Conclusions

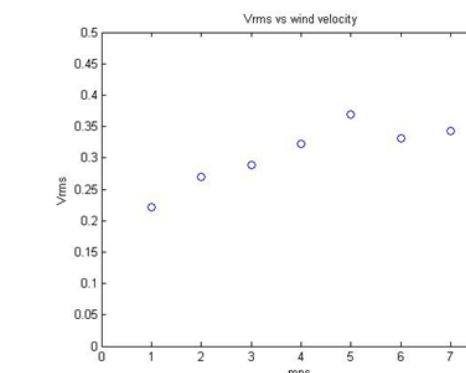

We began collecting the data. 10 seconds for each 1mps of wind velocity increase. Our range was between 0-mps and 8-mps (18 mph)

We also ran a continuous test increasing the mps every 60 seconds but running the program continuously. Notice the jump at 4mps.

We placed the data extrapolated from Matlab into an Excel spreadsheet and printed the graph
Note: voltage is represented as RMS Voltage

We also used Matlab to look at the amplitude of the voltage signal. Again it showed the highest amplitude between 4-5 mps.

Our goal for this research was to see if there was a correlation between wind speed and the amount of voltage that we could produce. Based on the data we collected, we feel that not only is there a correlation but that between 4 and 5 meters per second the ability of our sample peaked out the amount of voltage it could produce. Given time we could have trialed other sample shapes, areas, thicknesses to explore the optimum film and wind speeds for maximum voltage capture. Based on frequency vs amplitude 4-5 mps appears to maximize flag movement.
