1 Introduction

1.1 A Brief History of LyX

In the late 1970's a professor at Stanford University, Donald Knuth, was revising a multivolume set of books entitled *The Art of Computer Programming*, when he got back the galleys, looked at them, and said (according to him) “bleccchh.” A computer scientist by trade, Knuth decided to write his own document processing program to improve the way mathematics is typeset. The result of this ten to fifteen year endeavor was T_EX, which rhymes with “bleccchh.” It stands, according to Knuth, for the Greek letters tau, epsilon, and chi, though I'm not sure why he chose those letters. In the early 1980's, Leslie Lamport developed L^AT_EX, a document preparation system built for T_EX but with lots of bells and whistles designed to make your document-preparing life easier. Getting to the point, in the late 1990's a group of slackers cum computer scientists developed a partially (and, over time, increasingly) WYSIWYG document processor that creates L^AT_EX documents. For reasons I've yet to fathom but can't imagine are very deep, they decided to call it LyX.

1.2 Why Use LyX

First, why use any document preparation system? If the back of an envelope was good enough for the Gettysburgh Address, why isn't a sheet of notebook paper good enough for a project report? Let's keep this simple: you ain't Abe Lincoln. The fact of the matter is—for better or for worse—your work will always be judged partly, if not mostly, by its presentation. The more polished your reports are, the more impressed your boss and co-workers (and, more importantly here, your math professor) will be.

So why LyX? Certainly standard word processors like Wordperfect and Microsoft Word offer equation editors with which mathematics can be slapped onto the page. In fact, several companies are beginning to develop packages expressly for writing mathematics, for example Microsoft's MathType for Windows. For us, the advantage of using LyX is that it is on your calclab account, so I know everyone has access to a copy.

2 Starting LyX at Texas A & M University

You should have a calclab account assigned to you for M442 (I'll pass these out on the first day of class, or as soon as I get them). Log in and click on the six-pointed geometric figure in the bottom left corner of your screen. Go to **Applications, Mathematics** and choose **LyX**. (Alternatively, your student account *may* have a short-cut icon for LyX. Failing these two possibilities, you can also open a terminal window and simply type *lyx* at the unix prompt.) If LyX asks if you want to create appropriate directories or something, just let it. Otherwise, you're there!

3 LyX Basics

3.1 Creating a Simple Document

LyX should splash up a simple logo over a gray screen. If the screen isn't maximized, you can maximize it in the usual way, by clicking on the square in the upper right corner of the form. To create a document click on **File, New**. LyX will start a document, giving you one strip in which to write your first line. Usually, this will be your title, so type *Project 1*.¹ Once you've typed this in, click on the arrows just to the right of the word **Standard** and choose **Title** from the drop-down *environments* menu (you will have to scroll down to find this). Notice that LyX centers your text and makes it look large and bold, like a title should. Hit **Enter** now and LyX will add a line for you to continue with. In this next line, type your name as you would like it to appear in your reports, and then choose **Author** from the environments. Finally, let's start the first section of our report. Hit **Enter** and then type *Overview* on the new line. Use your environments menu again to designate this as a **Section**. Notice that you have two options when choosing a section, **Section** and **Section***. Using **Section*** indicates that you want to suppress section numbering.

Before taking a look at our handiwork, let's put at least a few words of text into our section. Hit **Enter** and type, *In this project we study a bunch of really cool stuff*. To take a look at what you've done, choose **View, DVI** (alternatively, type **Control-d**; that is, holding the **Control** key while depressing **d**). This simple command does a whole lot of stuff, of which all you need to know right now is that a page containing LyX's typeset version of your work should pop up onto the screen. Take a quick gander and then click on **Quit** to drop it back down. This might be a good time to save your work. Choose **File, Save As**, then type in the file name of your choice (typically with a .lyx extension) and click **Okay**. (Notice that **Control-s** also saves your document.)

An incredibly useful option that you should become aware of right from the start is **Edit, Undo**. As you might expect, this command will return your document to its state prior to your last command. Repeated applications can undo a series of commands.

3.1.1 Document Types

Before moving on to equations, figures and tables, let's take a look at a few optional document types (which LyX refers to as document *classes*). Click on **Document** and choose **Settings**. Notice that the current document class is *article*, which is the one I've primarily been using to prepare notes in this course. Click on the black arrow to the right of the document class box, and choose the next document class *article (AMS)*, then **OK** at the bottom of the screen. See what you think. To go back to your original document class, simply choose **Document, Settings** again, then choose **article**. Feel free to experiment and turn in your reports in whatever style you think is best. One caveat here is that occasionally when you move back and forth from one class to another, something gets permanently changed. My advice is to always save your work just before trying a new document class, and if you don't

¹Whenever I mean for you to type something in, I will put it in italics on the page. This in no way indicates that you should type it in italics into your document. (Though see Section 3.2 about fonts.)

like the new document class, just don't save the new result. In particular, **Edit**, **Undo** won't cut it here.²

3.1.2 Formatting Your Document

The **Document**, **Settings** menu offers a number of options for controlling the appearance of your document. Below, I list a few of these that I find particularly useful.

- † **Text Layout.** The second option is **Text Layout**. Here, you can choose the font and the font size for your article, and you can also set paragraph separation to be either *indent* (as is the case with the document you're currently reading), or *skip*, for which paragraphs are separated by short vertical spaces. (Your reports will typically be written in the indent format, while typeset homework will typically be in the skip format.) In the event that you choose *skip*, LyX allows you to choose the height of the space.
- † **Margins.** The fourth option is **Page Margins**. Choose this one and click on the box denoted **Default Margins**. This will allow you to customize the margins of your page. Most of the documents for M442, including this one, have been printed with one-inch margins all around (though the top and bottom of the page have additional spacing as well).
- † **Bullets.** The tenth option is **Bullets**. With this, you can control how bullets will appear in your document. One of the options is a dagger, used to the left of these points. In most cases, I recommend you use the simplest option possible, a bold dot.

3.2 Setting Preferences

In order to set preferences for your version of lyx, choose **Tools**, **Preferences**. The second option under the **Look and Feel** submenu is **screen fonts**, and this is where you will set the basic types of fonts that you'll be using for your documents. The **Roman** text, **Sans serif** text and **Typewriter** text can all be chosen from the associated drop-down menus, and the text boxes to the right let you preview your choices. One fairly safe bet is Times New Roman. The fourth option under the **Look and Feel** submenu is **Graphics**, and there is one option you might want to set here. LyX has a feature called **instant preview**. If this is on, then equations you type in are shown in almost the form with which they will appear in your final copy. This option is set **off** by default, and it's fairly convenient, so you might want to set it **on**. Finally, keep these changes by clicking on **Save** at the bottom of the page.

3.3 Changing Fonts

There are a number of ways to change the way your text will appear on the page. Hit **Ctrl-e** at the prompt and type *emphasized words*. Notice how any text you type following **Ctrl-e**

²So to speak.

appears in italics. E is for *emphasis*, and on the printed page this text will be in italics like *emphasized words* are here. If you type **Ctrl-e** again, your text will return to its basic font. To toggle back and forth, you can also click on the big capital E at the top of the screen. Another useful command to remember is **Ctrl-b**, which makes your text bold. For a much broader class of options, we'll go to the menu. Use your cursor to shade over some words in your document—how about *with fixed*—and then choose the **ab** icon from the main menu. Your main option here is **Family**, with which you can choose one of the fonts you set in **Setting Preferences**. Notice that you can change the texts' attributes simply by clicking **Apply**, so it's easy to experiment. Try things like different sizes and maybe underlining. Typically, you won't want to use too much of this in a scientific report, but it's good to know it's there. When you finish experimenting, simply click on **Close**.

3.4 Formatting Paragraphs

Paragraph options can be set from the icon just to the right of **ab**, with the horizontal lines. You can choose the alignment of your paragraph and also the spacing between lines.

3.5 Lists and Nesting Lists

Suppose you want to write up a list of projects studied in an undergraduate modeling course. Begin by starting a new line and typing in the first project, *Ballistics Project*. With your cursor still to the right of *Ballistics Project*, click on the environments and choose **itemize**. The asterisk that appears to the left of *Ballistics Project* indicates that a bullet will set that text off from the main text (see Section 3.1.2 above for a brief discussion of bullets). Now, hit **Enter**, and LyX will prompt you with another bullet, expecting you to continue your list. Oblige by typing the first analytical section of the ballistics project, *Analysis in the absence of air resistance*. Strictly speaking, *Analysis in the absence of air resistance* should be part of a sub-list, so while the cursor is at the end of the phrase, choose the blue right-directed arrow from the main menu to set it. Observe that LyX indents the phrase to indicate that it's in a sub-list. Continuing similarly, see if you can typeset the list below.

- † Ballistics Project
 - ▷ Analysis in the absence of air resistance
 - ▷ Linear air resistance
 - ▷ Nonlinear air resistance
 - Dimensional analysis
- † Queueing Theory Project
 - ▷ Identifying Distribution functions
 - Etc.

To get out of the nesting environment, simply choose **standard** from the main drop-down menu.

3.6 Special Formatting

In order to choose such things as additional space between text, vertical spacing between paragraphs, horizontal lines in the text, linebreaks and page breaks, choose **Insert, Special Formatting**.

3.7 Inserting Equations

One of the main reasons we're using LyX is because we plan to write lots and lots of equations. Let's start off simple with something in-line, like, $y = x^2$. We might try the sentence, *This project doesn't actually use the equation $y = x^2$* . When you get to the equation, click on the button at the top of your screen with the blue $\frac{a+b}{c}$ on it (alternatively, type the sequence **Control-m**). You'll notice that the cursor changes, beginning to glow, a reddish outline around a blue box. Don't worry, that just means you are now officially in equation-producing mode. Type $y=x^2$, and notice how LyX automatically typesets the 2 for you as a superscript. Hit your right arrow key twice now (once to get away from the superscript and once to get out of the equation editor), and LyX will exit its equation editor and let you get back to the text. Before moving on to display equations, let's do something just a little fancier in-line. How about $\sqrt{\cos^2 \theta}$? First, click on the in-line equation editor again to put LyX in the right frame of mind. (That's the $\frac{a+b}{c}$ button.) Now, from the top menu, choose **Insert, Math, Math Panel**. A menu of math symbols should appear somewhere on your screen. If this turns out to be in your way, you can always move it simply by clicking on its blue strip at the top and dragging it. To get started on the square root, click on the square root sign in the upper left corner of the panel. This allows you three possibilities, of which, here, we want the first, *Square root*. Once you've got a square root in place, you will have to click on it to let LyX know you're finished with the **Math Panel**. (You will often be writing an equation with several parts, so you may want to leave the **Math Panel** up.) Back in the math environment, don't just type \cos underneath the square root—that will look tacky. On second thought, go ahead and type it in. See? Tacky. Okay, delete it and choose the word \cos from the functions in your **Math Panel** (you will need to double-click on it). Notice how the letters appear like text instead of as variables. In order to square \cos , you will need to click on your equation again to get its attention (clicking on the blue strip at the top of your main document will suffice) and type 2 , then the right arrow (to get out of superscript mode). Finally, go back to your Math Panel and select **Greek** from the **Symbols** menu. Click on the theta (θ) to finish off our expression and then use the right arrow key a few times to get out of the equation editor.

Often, equations are going to get so long for us that it will be unwieldy to include them in a line of text. These, we will separate out, like

$$\frac{x^2+1}{y^2} = \frac{z/5}{w^8}. \quad (1)$$

In order to do this, simply stop wherever you happen to be in a line and click on **Insert, Math, Display Formula**. Once you are in display equation mode, the rules are just like for in-line equations. If you can copy the one just above, you're probably in pretty good shape. When you are finished with the equation, simply use your right arrow until your cursor is

directly to the right of the equation box and the equation box is no longer lit. Now, you're ready to get back to business. By the way, you can create subscripted expressions, like a_1 by typing `a_1` in math mode.

If you're going to refer back to your equation, you will want to label it. Do this by first clicking on your equation, then choosing **Insert, Label**. A box will appear on your screen, in which your label has already been started as `eq:` to remind you that this is an equation. Type in some label, say, `eqn1`. Finally, if you want to refer to this equation, choose **Insert, Cross Reference**, and then select it from the list.

While most of the options in LyX's equation editor are straightforward, a few are pesky. One issue that's oddly tricky is typing regular text into an equation. For example, you might want the equation

$$\text{Force} = \text{mass} \times \text{acceleration}.$$

How do you get Force, mass, and acceleration to appear as regular text instead of—as is LyX's default—as individual variables. The secret here is *while in equation mode* click on the button $\frac{a+b}{c}$ (alternatively, type **Control-m**). LyX will allow you to type regular text.

Remark for L^AT_EX experts: If you happen to know a bunch of L^AT_EX commands, you'll certainly begrudge having to choose things like radical signs from pop-down menus. Not to worry. In equation mode, LyX lets you use your L^AT_EX expertise in a convenient way. Start an in-line equation by choosing again the button $\frac{a+b}{c}$ (if you get tired of that button, you can accomplish the same thing with **Control-m**). Now, instead of bringing up the Math Panel and choosing a radical sign, type simply `\sqrt` (that's a backslash, not a vertical line), followed by the space bar. LyX will go ahead and create the radical for you, and set your cursor inside it. Try it with other L^AT_EX commands until you get comfortable. Finally, if you've forgotten the L^AT_EX command for some symbol, you can find the command by looking up the symbol on the math panel and let your cursor linger over it for a moment.

3.7.1 Aligning Equations

You may find yourself writing systems of equations in your reports, something like

$$\begin{aligned} x &= a + b \\ y &= c + d + e + f \end{aligned}$$

Probably the easiest way to accomplish something like this is to choose **Insert, Math, AMS Align Environment**, which automatically begins a display formula, with two boxes. In this case, we will align the equal signs, so type `x=` into the first box and then use the right arrow key to move your cursor over to the right box. Write out the first of the equation in the right box, and then type **Ctrl-Enter** to create a second line, giving you four boxes altogether. On the second line type `y=` into the left box and the remainder of the equation in the right.

3.8 Inserting Figures³

Our main source of figures in M442 will be MATLAB graphics saved as encapsulated postscript files, so that's what we will look at. Suppose you have the file *figure1.eps* lying around somewhere on your directory. In order to incorporate it into your document, first insert a *Figure Float*. To do this, hit **Enter** to begin a new line (this step is critical! If you get an error message later, this may be the step you skipped), and then choose **Insert**, **Float**, and then **Figure** from the small pop-up window. (A figure float can also be inserted directly from the the figure icon on the lower icon bar of the main menu.) A red rectangle should appear on your screen, with the expression **Figure #:** in its center. Place your cursor inside this rectangle, just to the right of **Figure #:** and type in a caption for your figure, something like, *This is our first figure*. Next, move your cursor back to the beginning of your caption and hit **Enter**. Your caption line should drop down a vertical space, and your cursor should move to the top left corner of your figure float. From the main LyX menu, choose now **Insert**, **Graphics**, then, under the **Graphics** tab, select the **Browse** option and sift through your files until you find one that is encapsulated postscript. (A figure can also be inserted directly from the the figure icon on the upper icon bar of the main menu.) Once you've selected your figure by choosing **Ok**, you will need to choose an appropriate size for it. On the same form you chose your figure from, click on the right arrow next to *Scale%* and choose units, say *cm*. Make your figure 4 centimeters wide and 4 centimeters tall. (You will need to set units separately for both width and height.) Finally, choose **OK**. One final thing you might want to do is center your figure. For this, simply use your mouse to shade your figure, and choose the **Paragraph Setting Alignment** as **center**. (Recall that the Paragraph Settings menu can be selected with the icon to the right of **ab** with horizontal lines.)

Figure 1: This is our first figure.

In case we need to refer to this figure later on, let's give it a label. Put your cursor at the end of your figure's caption and click on **Insert**, **Label**. (You can also click on the label icon on the lower icon bar of the main menu.) A window will pop up with a single line, allowing you to type in a name. Once you have done this and clicked on **OK**, a button will appear in your figure telling you what its label is. If you want to refer to your figure later in the document, don't do the obvious thing: *See Figure 1*. Write *See Figure* , (the space before the

³Before beginning this section, you will need an *encapsulated postscript file (.eps)* somewhere on your directory. If you don't already have one, go to MATLAB and create one. You should be saving all of your MATLAB figures as both *.eps* files and *.fig* files.

comma is *sic*) then click on **Insert, Cross Reference**, and choose Figure 1 from the list of possibilities (the list should be fairly short at this point). (Once again, you can alternatively insert a reference with the Insert cross-reference icon on the lower icon menu.) All that big gray box does is put a 1 in your document, so why have we gone to all this trouble? I'll tell you why. If later, you decide to put a second figure before this one, you won't have to go through your document rooting out all your Figure 1's. LyX will automatically make this one Figure 2 and update all your references. This trick is especially important with equations, for which there may be many and for which the labeling procedure is almost exactly the same (see Section 3.5).

3.8.1 Positioning Floats on the Page

One nice thing about using a figure float is that it makes it easy to position your figure on the page. In order to choose your preference on how your floats should be placed, choose **Document, Settings, Float Placement**. In most cases, you will want your figures to appear where you place them in the document, and in this case you will want to choose the option **Here if possible**. If you additionally choose **Top of page**, then if for some typesetting reason LyX cannot place your float exactly where it appears, then it will place your float at the top of the page. The bad news is that currently LyX does not allow you to position each figure in your document separately. However you set one of them, you must set all others the same way. I would imagine this is something that will be changed in further versions. In any case, hit **OK** now, and let's move on to inserting files.

3.9 Inserting Text Files

Your M442 project reports will almost certainly include at least a few M-files and maybe some diary files as well.⁴ Both types are in ASCII text format, which means they are extremely easy to incorporate into a document. Suppose, for example, you happen to have the file *mfile.m* lying around somewhere on your hard drive. To incorporate it into your document, simply click on **Insert, Insert File**, then from the pop-up menu **Place text as Lines**. Search through your drive until you come across the file and double click on it. The text should immediately appear on your screen. To set it off a little, use your mouse to select it all, and then from your options in the environments menu, choose **Quotation**. The final product should look something like the file included below.

```
function factorial = fac(n);
%FAC: Computes the factorial of n
factorial = 1;
for k=2:n
factorial = factorial*k;
end
```

Inserting diary files is just as easy; see the handout *MATLAB Basics* for plenty of examples of how diary files should end up looking. If you want your diary file to mimic the spacing

⁴If you're not sure what these are, consult your notes, *MATLAB Basics*.

of MATLAB's output, use **Quote** rather than **Quotation**. A brief MATLAB session is included below, first as a quotation, and next as a quote. I have added MATLAB's command line prompt `>>` at the beginning of each MATLAB command to distinguish it.

```
>>x=sin(pi)
x =
1.2246e-16
>>x=cos(pi)
x =
-1
```

```
>>x=sin(pi)
x =
1.2246e-16
>>x=cos(pi)
x =
-1
```

By the way, when you start typing text underneath your M-file or diary file, LyX will think you are still quoting. Simply click on the environments menu again and choose **Standard**. Now you're back in business.

3.10 Creating Tables

Especially if you are working with experimental data, you will want to tabulate certain values. Unfortunately, this is not LyX's long suit. Nonetheless, let's see how we can create a workable table. For example, suppose in this global economy, you decided to study trends in world migration. You might want to tabulate, say, the average annual net migration between 1996 and 2001 for various countries. In order to begin a table, hit **Enter** to start a new line, then choose **Insert, Float, Table**. (Alternatively, there is a table float icon just beside the figure float icon on the second row of icons.) As with figures, type in an appropriate caption and then position your cursor to the left of the caption and hit **Enter**. Next, choose **Insert, Table**, and select a table with two columns and five rows (like the one below). (You're probably getting tired of hearing this, but there is also an **Insert Table** icon beside the **Insert Graphics** icon.) A matrix will appear in your screen, allowing you to type whatever data you have into the spots. Fill it in like Table 1 on this page, except don't worry yet about the formatting. You will notice that your table doesn't look quite like Table 1. To shape it up, set your cursor on any of the country boxes and select **Edit, Rows & Columns**, then **Left** (for left align) from the pop up menu. Do the same thing with the numbers, aligning them on the right. Now, let's center the entire table. Select the entire table by shading it with your mouse and choose **Paragraph Settings**, and the alignment as justified (as in the case with figures).

United States	960,000
China	-508,000
Germany	311,000
Afghanistan	289,000
Mexico	-284,000

Table 1: Most active countries in world immigration.⁵

3.11 Printing a LyX Document

We will print our LyX documents out as *pdf* or *postscript* files, then print these files with *xprint*. Since signs all over Blocker tell you how to print using *xprint*, I'll focus on the LyX part. For postscript, once your document is finished and saved, choose **File, Print**, then under **Print Destination**, choose **File** and pick the directory and filename you want, making sure it ends .ps. For *pdf*, choose **File, Export** and select the *pdf (ps2pdf)* option.

3.12 Getting Help

LyX doesn't yet have the absolute best Help file going, but the help is getting better with each version. A good way to use what they do have is this: Click on **Help, User's Guide**, then once the User's Guide comes up type **Ctrl-f** to search it. Now just search for whatever topic it is you need help on. Notice that when discussing key-bindings the LyX help notation *M-key* indicates that **Alt** should be followed by the letter *key*. For example, *M-a* indicates that the user should use the sequence **Alt-a**. A postscript or .pdf version of the User's Guide can be printed just like any other LyX document (see Section 3.11). Also, the designers have some on-line help at the web site www.lyx.org.

4 Advanced Topics

As of the writing of these notes, some LyX applications still require L^AT_EX code. In this section, I'll mention a few of the most useful.

4.1 Adding an Index

L^AT_EX preamble can be added to any LyX document by choosing **Document, Settings** and then **L^AT_EX Preamble** from the left menu. An index can be added to your document with the following lines in this preamble:

```
\usepackage{makeidx}
\makeindex
```

Once this is done, simply move to the end of your document (or wherever you want the index placed) and choose **Insert, List/TOC, Index List**.

⁵Source: U.S. Bureau of the Census estimates and projections. A negative value indicates emigration. I should probably add that I don't have any political agenda here. For reasons entirely unrelated to M442, these numbers just happened to be on my desk.

4.2 Formatting Equation, Figure and Table Counters

By default, LyX will label equations in your document 1, 2, 3, ... etc. without regard to sections and subsections. You can change this by adding the following lines to your preamble:

```
\renewcommand{\theequation}{\thesection.\arabic{equation}}
\numberwithin{equation}{section}
```

Figures and tables can be labeled similarly by changing *equation* to *figure* or *table* respectively each time it appears.

4.3 Headers

It's possible to add a header to a LyX document, like the one running along the top of this page, which was created with the following lines:

```
\usepackage{fancyheadings}
\pagestyle{fancy}
\lhead{M442}
\chead{LyX 1.4.1}
\rhead{P. Howard}
%Width of line below running headers
\setlength{\headrulewidth}{1pt}
```

The *style* file *fancyheadings* needs to be on your machine for this to work.

5 FAQs

In most cases, I've tried to answer the questions of students from years past by putting the material directly into the text of this tutorial. In cases where the question didn't seem to fit anywhere, or where it was so frequently asked that I thought it wise to put its answer somewhere easy to find, I've set it here.

- 1. How can I get vector arrows over a variable?** From the **Symbols** menu in the **Math Panel**, choose **Frame Decorations**.
- 2. How can I keep LyX from starting a new paragraph after I type in an equation?** If you don't hit **Enter** after typing in an equation, LyX won't start a new paragraph. You actually have to start typing before LyX will set your cursor on the next line.
- 3. Why are my equation labels appearing on the lines following my equations?** This happens when you exit your equation before choosing **Insert, Label**. Make sure you're still in equation mode when you insert the label.
- 4. How do I get rid of all these red error messages?** First, I recommend looking at the finished product of your LyX document frequently enough that the red error messages don't add up. While it's fairly easy to hunt down and eliminate one or two, if you have twenty document pages and sixty-three error messages, you're in for a late night. Of course, there's no single specific cause of these errors, though two common causes are figures and plain text

appearing in equations. With figures, the problem is typically that the figure frame was created at the end of a line of text rather than on its own line. (You didn't hit **Enter** when you started to import it.) This is a particularly insidious problem because there is no way to see that you've made this error and the only way to fix it is to delete the entire figure float and start over. Similarly, LyX often struggles with plain text typed into an equation. For this one, I honestly just don't know how LyX decides what it likes and what it doesn't, and again, you can often fix the problem simply by deleting the equation and typing exactly the same thing again. More generally, the best thing I can tell you is that the error is *usually* near the error message, and often you actually have to pinpoint it by deleting chunks of text and trying to view your document.

5. Can I get my own copy of LyX? Yes, and it's free. At this point, there are versions for just about any platform: Linux, Windows, Apple etc. You'll find all the information you need at the LyX web site www.lyx.org.

6. Why do my PDF documents look fuzzy, and how can I fix it? They look fuzzy because as of January 2005 there was a font incompatibility problem with LyX's documents. In order to fix this, you need to manually tell LyX what font to use. Proceed as follows: From the main LyX menu, choose **Edit, Preference**, and in the left column of the dialogue box that appears, click on the + next to **Outputs** to expand the category. Select **LaTeX**, and in the right side of the dialogue box at the top, change the TeX encoding to OT1 (capital O, capital T, numeral 1). Click on the **Save** button at the bottom of the dialogue box.
